Assoc Prof  
MATUBAYASI, Nobuyuki  
(Ph D)

Assist Prof  
WAKAI, Chihiro  
(D Sc)

Program-Specific Res  
KARINO, Yasuhito  
(D Sc)

Program-Specific Res  
SAKURABA, Shun  
(D Sc)

PD  
PURQON, Acep  
(D Sc)

### Researchers

KUBOTA, Yoshiyuki  
FURUKAWA, Hirotoshi

### Students

KIMURA, Hiroshi (D2)  
SHINTANI, Megumi (D2)  
ZENIYA, Yuki (M2)

SAKAI, Yoshiyuki (M2)  
MATSUO, Yushi (M1)

### Visitors

Mr MARSALEK, Ondrej    Czech Academy of Science, Czech Republic, 25 January–31 March  
Dr FEDOROV, Maxim V    Max Planck Institute, Germany, 12–14 March

## Scope of Research

The structure, dynamics, and reaction of solutions with nano-scale inhomogeneity and/or with fine tunability are investigated by NMR spectroscopy, computer simulation, and statistical-mechanical theory of solutions, and vibrational spectroscopy. Solvation is systematically elucidated for ionic liquids and supercritical fluids from both the static and dynamic viewpoints, and noncatalytic reactions of environmental importance are developed. The structural organization and fluctuation and the molecular binding are investigated for soft, self-organizing systems such as micelle, protein, and lipid membrane.

### KEYWORDS

Lipid Membrane  
Supercritical Fluid  
Ionic Liquid  
Free Energy  
Dynamic Inhomogeneity

## Dynamical Inhomogeneity of Lipid Membrane

The dynamical inhomogeneity in the lipid membrane is studied over a wide range of curvature by the solution-state  $^1\text{H}$  NMR-nuclear Overhauser effect (NOE). To make possible the NOE measurement for large vesicles, the transient NOE method is combined with the spin-echo method (transient NOE-SE method) and is applied to micelle of 1-palmitoyl-lysophosphatidylcholine (PaLPC) with a diameter of 5 nm and to vesicles of dipalmitoylphosphatidylcholine (DPPC) with diameters ranging from 30 to 800 nm. The transient NOE-SE method suppresses the broad components in model-membrane signals and enables quantitative assessment of the NOE intensities even for an almost flat bilayer of  $\sim 800$  nm in diameter. It is found that the NOE intensity increases with the diameter up to  $\sim 100$  nm, and the model membrane is considered flat beyond  $\sim 100$  nm. While the NOE between the hydrophilic choline and hydrophobic terminal methyl groups is absent for micelle as expected, its intensity is comparable to that for the neighboring group for vesicles of larger diameters. The origin of NOE signals between distant sites is revealed by MD analysis. The MD simulation is performed for the PaLPC micelle and the DPPC flat bilayer, and the time correlation function determining the NOE cross intensity is calculated. The corresponding correlation time for the DPPC flat bilayer enhances to microsecond and is shown to yield an observable NOE signal even for the hydrophilic terminal and hydrophobic terminal sites. Since the correlation time depends on the proton pairs by orders of magnitude, the NOE intensity for large vesicle is combined information of distance and dynamics and does not reflect only the distance. The correlation time in large vesicle is then determined by employing the experimental NOE intensity and the MD-based distance distribution. It is found to vary by three orders of magnitude over the proton sites in the case of large vesicles.

**Figure 1.** The vesicle size dependence of the cross relaxation rate constant  $\sigma$  between the  $\gamma$  site and the other sites at  $60^\circ\text{C}$ .

## Free-Energy Analysis of Hydration Effect on Protein with Explicit Solvent

Hydration is a key factor for controlling the stability and fluctuation of protein structure. In the statistical thermodynamic context, the hydration effect is quantified by the solvation free energy and is affected by specific protein-water intermolecular interactions. In the present work, the relationship between the protein conformation and the hydration effect is investigated for the equilibrium fluctuation of cytochrome *c*. To elucidate the hydration effect with explicit solvent, the solvation free energy of the protein immersed in water was calculated using the molecular dynamics simulation coupled with the method of energy representation. As shown in Figure 2, the protein intramolecular energy and the solvation free energy are found to compensate each other in the course of equilibrium fluctuation. The energy variation corresponding in magnitude to the formation/breakage of several tens of hydrogen bonds is induced and compensated by the solvent water. The correlation of the solvation free energy is further examined against the average sum of protein-water interaction and the excluded-volume part of the solvation free energy. The average sum is dominated by the electrostatic interaction and varies in proportion to the solvation free energy. The excluded-volume part has no correlation to the (total) solvation free energy and is virtually constant. The variation of the solvation free energy in response to the conformational fluctuation at equilibrium is described by the linear-response-type relationship with the protein-water interaction supplemented by an offset representing the excluded-volume effect.

**Figure 2.** The solvation free energy  $\Delta\mu$  of cytochrome *c* plotted against the intramolecular energy  $E_{\text{intra}}$ . The solid line represents the least-square fit and is given by  $E_{\text{intra}} + \Delta\mu = -1.7 \times 10^3$  kcal/mol.
